

Generated 2026-10-06 from branch `claude/practical-hamilton-sspq2e`, file `pvv_score/results/REPORT.md`. Ranking as of the 2026-10-05 close.

PVV Score: price / volume / volatility selection for 21-63 day forward risk-adjusted returns

Universe: 503 Finviz S&P 500 constituents (file `data/universe_finviz.csv`), sector mapped to SPDR ETF. Data: yfinance daily OHLCV, dividend/split adjusted, 2012-2026-10-05. Backtest window 2014-01-01 onward; **the 2022-10 onward window ('recent') is the primary evidence** per the mandate, the full window is the secondary check.

All statistics are out-of-sample where labelled OOS. Nothing here uses fundamentals, earnings or valuation.

1. Bottom line

- Two readings carry out-of-sample signal for 21-63d forward Sharpe in this universe in the current regime: relative-strength leadership (`rs_lead_126` : RS line nearer its 6-month high than price is to its own) and 12-1 momentum. Both survive beta-neutralisation (recent-window 42d IC 0.03-0.05, NW t 2.1-2.4). Both were dead 2014-2021.
- The setup that works depends on beta. High-beta names: buy persistence (momentum, trailing Sharpe, proximity to highs, recent 2x-off-low crossings; the 100%-off-low ceiling is the wrong sign there). Low-beta names: price-structure factors die and quiet volume-led accumulation takes over (volume dry-up vs 250d, falling dollar volume, OBV leading price, shallow drawdowns, low idiosyncratic vol, and the dry-up x tight-range x near-high interaction).
- The live ranking (`current_rankings.csv`) is the within-beta-bucket walk-forward composite built from those weights: recent-window OOS 42d IC 0.047, 63d 0.065, top-vs-bottom decile 42d Sharpe spread +0.29 annualised, 57% of windows positive. A pooled (beta-blind) composite has no edge.
- Roughly half to two thirds of the ranking is ticker identity (names that are chronically near highs, drawdown-free and high-Sharpe) rather than a current state change; the state-change half is weaker (IC 0.035) and is led by momentum and RS leadership that are unusual for the name (section 7).
- Compression / NR7 / Bollinger squeeze, ignition-day volume multiples, accumulation-day counts, gap behaviour, streaks and close-location factors showed no 1-3 month signal in S&P 500 names, pooled. The LightGBM case-study model, in five configurations, did not beat the

two single factors out of sample (recent 42d IC 0.00-0.02) and is reported but not used in the ranking.

2. Method

- Targets.** For every (date, stock): realised Sharpe and Sortino of the stock over $t+1..t+h$ ($h = 21, 42, 63$) minus the same for SPY and for the stock's sector ETF (XLRE/XLC spliced to XLF/XLK before inception). Also the information-ratio form (Sharpe of stock-minus-SPY). The ML label is the per-date percentile of SPY-excess Sharpe averaged over the three horizons.
- Eligibility (point-in-time).** Price $\geq \$5$, 63d median dollar volume $\geq \$10M$, ≥ 252 sessions of history. Survivorship caveat: the universe is today's constituents, so absolute levels are biased up; cross-sectional ranks are far less affected.
- Factors.** 86 point-in-time factors in five families (price structure, volume, volatility, relative strength, run character) plus two user-described interaction setups. Each verified against hand calculations and a perturbation test for look-ahead (none).
- Statistics.** Daily cross-sectional Spearman IC; Newey-West t-stats with lag = horizon because forward windows overlap; Benjamini-Hochberg across the 86-factor zoo; decile spreads in raw excess-Sharpe units; 21-day rank autocorrelation (turnover).
- Conditioning.** Everything re-run inside trailing-beta terciles, 20d realised-vol terciles, sector groups (defensive / cyclical / growth), per sector, and with sector-neutral ranks.
- Case-study model.** LightGBM trained walk-forward by calendar year (2017-2026), 63-day embargo, 2-year half-life time-decay weights, every 5th day sampled for training. Four pre-specified regularised variants were also run. Nearest-neighbour analogs (50 historical cases, max 3 per ticker) give each live name its realised-outcome evidence.
- Composite.** Factor selection and weights re-estimated each year on training data only ($|NW\ t| \geq 1.5$ on the trailing 3y, sign agreement with full history, greedy de-duplication at $|\rho| > 0.7$, weights = recency-blended IC). Pooled and beta-bucketed variants.

3. Single-factor results (SPY-excess Sharpe, mean IC across 21/42/63d)

Power note: the recent window is ~1,000 sessions = roughly 24 independent 42-day windows, so $|t|$ around 2 is the attainable ceiling for a genuine IC of 0.05-0.07. **No factor survives Benjamini-Hochberg at 5% in either window.** The evidence is in coherent clusters, not individual rows.

`d10_d1_spread_recent_42` is the annualised 42d Sharpe difference between the factor's top and bottom decile (recent window). `autocorr_21` near 1 = slow factor; near 0 = daily-turnover factor.

Reading of the clusters

- **Trend-persistence / leadership cluster** (`rs_lead_126` , `mom_12_1` , `dist_52w_low` , `up_capture_63` , `days_since_2x_low` negative, `ceiling_2x_low` positive): the only group with a consistent positive sign in the recent window and a positive sector-excess reading. Note `ceiling_2x_low` comes in with the OPPOSITE sign to the prior: names already 100% off their 52w low have continued to produce better forward Sharpe in 2022-2026. In the pooled sample the "ceiling" is not a ceiling.
- **Beta / correlation cluster** (`beta_63` , `beta_252` , `corr_spy_63` , `rv20` , `dn_vol_63`): positive in the recent window, flat over the full window, negative vs sector. This is the bull-regime beta bet,

not stock selection. The composite and the model are therefore also evaluated beta-neutral (section 5).

- **Compression / dry-up setups** (`range_comp_*`, `bbw_*`, `nr7_count_20`, `vol_dry_*`, `dryup_x_tight`): no pooled signal at these horizons. They show up only conditionally (section 4), in low-vol / defensive names.
- **Ignition / volume-burst factors** (`ignition_mult_10`, `vol_z_1`, `big_vol_updays_net_21`, `ignite_x_rs`): no signal for 21-63d forward Sharpe in S&P 500 names. These are shorter-horizon or small-cap phenomena.
- **Short-term price factors** (`ret_5`, `clv_5`, `streak_now`, `pos_in_20d_range`): nothing. Daily-turnover factors with no 1-3 month payoff.

4. Conditional results: where each factor works (recent window, 42d, NW t-stats)

Multiple-testing note: 86 factors x 10 buckets = 860 tests; the expected maximum $|t|$ under the null is about 3.2, so single cells near 3 are not individually reliable. What is reliable is the pattern:

- **High beta / growth:** the trend-persistence cluster is strongest here (`mom_12_1` $t=3.6$ in the high-beta tercile, `days_since_52w_high` -2.5, `ceiling_2x_low` +2.7, `days_since_2x_low` -2.7). In high-beta names, buy strength, recent 2x-off-low crossings, and proximity to highs.
- **Low beta / low vol / defensive:** the sign of several price factors flips or dies, and volume-structure factors appear instead: `obv_price_div_63` +3.6 in defensives (volume leading price), `vol_dry_20_250` -2.1 in the low-vol tercile (dry-up works for utilities/staples-type names), `dvol_trend_21_126` -2.9 in low beta (quiet names outperform), `idio_vol_63` negative in low/mid beta. This is the DUK-vs-NVDA asymmetry the mandate anticipated, and it is why the composite is fitted per beta bucket.
- **Per sector** (`conditional_ic_42_per_sector.csv`): indicative only (18-80 names per date). Notable: Utilities `rs_lead_126` +3.1 and dry-up negative; Consumer Defensive `ceiling_2x_low` -3.2 (the ceiling DOES hold in staples) and compression factors positive; Financials show reversal (`ret_63` -2.3).

5. Out-of-sample predictive models (walk-forward 2017-2026)

6. Live scoring

`current_rankings.csv` columns: `final_score` = within-beta-bucket composite percentile (the ML percentile is reported alongside, not blended, because of its OOS record);
`analog_med_xsSharpe42` / `analog_pct` / `analog_hit_rate` = realised 42d SPY-excess Sharpe of the 50 nearest historical cases (median, its percentile across today's names, share > 0); key factor readings follow.

7. Ticker identity vs. behaviour: how much of the signal generalises across tickers

Each reading is split, point-in-time, into **persistent** (the ticker's own expanding-window mean up to t-1: "this ticker is usually like this") and **deviation** (today's reading as a z-score against the ticker's own history: "this ticker is currently unusual"). IC of each component vs 42d SPY-excess Sharpe:

| factor | recent|raw | recent|persistent | recent|deviation | full|raw | full|persistent |
full|deviation | |:------:|-----:|-----:|-----:|-----:|-----:
-----:|-----:|-----:| | comp_bucketed | 0.047 | 0.053 | 0.035 | 0.015 |
0.017 | 0.016 | | corr_spy_63 | 0.077 | 0.055 | 0.058 | 0.028 | 0.033 | 0.007 | |
days_since_20pct_dd | -0.008 | -0.043 | 0.021 | 0.009 | 0.006 | 0.008 | | dist_52w_high | -0.004
| -0.032 | 0.005 | 0.009 | 0.015 | -0 | | dryup_x_tight | -0.003 | -0.015 | 0.001 | 0.006 | 0.018 |
0.001 | | idio_vol_63 | 0.006 | 0.028 | -0.018 | -0.024 | -0.008 | -0.017 | | mom_12_1 | 0.039 | 0.019
| 0.044 | 0.007 | 0.022 | 0.003 | | obv_price_div_63 | 0.01 | 0.023 | 0.007 | 0.006 | 0.01 | 0.004 | |
rs_lead_126 | 0.068 | 0.067 | 0.031 | 0.004 | 0.032 | -0.013 | | sharpe_126 | 0.016 | 0.009 | 0.012 |
0.003 | 0.021 | -0.006 | | up_capture_63 | 0.073 | 0.064 | 0.028 | 0.014 | 0.021 | -0.007 | |
vol_dry_20_250 | -0.01 | -0.021 | -0.009 | 0.001 | -0.018 | -0 |

Pure ticker-identity predictors (long trailing Sharpe; the ticker's own trailing-year mean realised excess Sharpe):

| predictor | ic|full | ic|recent | t_nw|full | t_nw|recent | |:------:|-----:|-----:
-:|-----:|-----:| | past_xs_1y_mean | 0.015 | 0.044 | 0.927 | 1.699 | | sharpe_252 |
0.013 | 0.042 | 0.758 | 1.615 | | sharpe_504 | 0.013 | 0.026 | 0.651 | 0.865 | | sharpe_756 | 0.024 |
0.034 | 1.266 | 1.303 |

Reading:

- The out-of-sample composite's recent IC (0.047) is matched by its persistent component alone (0.053); the deviation component carries 0.035. Today's composite rank correlates 0.580 with the ticker's own historical-average composite rank. **Roughly half to two thirds of what the ranking expresses is which tickers are chronically strong and stable, not a current state change.**
- A ticker's own trailing-year mean realised excess Sharpe predicts its next 42 days with IC 0.044 (t 1.7) in the recent window, about the same as the whole system. In 2022-10 to 2026 leadership

persisted at the ticker level; much of the system's recent edge is that persistence.

- The persistent component is the part most exposed to survivorship bias (today's constituents are disproportionately the names that were chronically strong). Treat the identity half of the score as regime- and universe-dependent.
- The deviation component is the cleaner "behaviour predicts across tickers" evidence. It is weaker but real: 12-1 momentum unusually high for the name (IC 0.044, t 2.0, the only reading where the state component beats the identity component), RS-line leadership unusual for the name (0.031), correlation to SPY unusually high (0.058), idiosyncratic vol unusually low (-0.018). Proximity to 52w high, time since 20% drawdown and the dry-up interaction have no deviation signal pooled: they work only as identity, and only inside beta buckets.
- Volume factors: `obv_price_div_63` and `vol_dry_20_250` show up as identity, not state, pooled. The names that habitually have volume leading price, or habitually dry up, do better; a dry-up that is unusual for the name does not.

8. What to trust, what not to

Direct read of the evidence, in order of reliability.

1. What has out-of-sample support for 21-63d forward Sharpe in this universe

- Relative-strength leadership: `rs_lead_126` (RS line closer to its 6-month high than price is to its own). Walk-forward baseline, recent window: 42d IC 0.068 (NW t 2.4), 63d IC 0.082 (t 2.7); still 0.034-0.041 (t 2.1-2.2) after removing beta. The single most useful reading in the library.
- 12-1 momentum: recent beta-neutral 42d IC 0.048 (t 2.4), sector-excess IC 0.043 (t 2.1). Dead over 2014-2021 (full-window IC 0.005), alive since 2022-10. Consistent with the regime shift the mandate describes.
- Beta-bucketed walk-forward composite: recent 42d IC 0.047 (t 1.5), 63d 0.065 (t 1.9), top-minus-bottom decile 42d Sharpe spread +0.29 annualised with near-monotone deciles. The pooled composite has nothing (recent IC negative). Conditioning on beta is what makes the composite work. Its beta-neutral IC is small (0.006-0.015): inside each bucket it still leans on correlation / up-capture type factors, so part of its recent edge is bull-regime beta.
- Low-beta / defensive names respond to volume structure, not price structure: OBV leading price (`obv_price_div_63` , t 3.6 in defensives), volume dry-up vs 250d (`vol_dry_20_250` , t -2.1 in the low-vol tercile), falling dollar volume (`dvol_trend_21_126` , t -2.9 in low beta). Treat as a cluster, not three independent facts.

2. What did not show signal at this horizon in S&P 500 names (tested, not assumed)

- Compression setups (daily-range percentile, Bollinger width, NR7 clusters, base tightness), pooled: IC within ± 0.015 in every window and horizon. They only appear inside the low-vol / defensive bucket. The "compression then expansion" sequence factor is flat everywhere.
- Ignition-day volume multiple, volume z-score, big-volume up-day counts, the ignition x RS interaction: flat. Nothing in a 1-10 day volume burst predicts the next 1-3 months of risk-adjusted return here.
- Accumulation/distribution day counts, up/down volume ratio: flat pooled, mildly negative in places.
- Higher-low cadence, close location value, gap frequency, streaks, 20d range position: flat.
- The 100%-off-low "ceiling": wrong sign pooled and in high beta (names already 2x off the low kept producing better Sharpe, $t +2.3$ to $+2.7$); right sign only in Consumer Defensive ($t -3.2$). Do not use it as a universal exclusion.
- The LightGBM case-study model, in all five configurations: recent-window 42d IC between -0.001 and $+0.023$, none significant, every variant below the two single-factor baselines. A great 2019 (IC 0.11-0.14) and nothing stable since. Non-linear interaction mining over 86 factors does not beat two robust factors at this horizon with ~ 10 years of 500-name data. The analog columns in the ranking are therefore descriptive evidence per name, not a forecast.

3. Statistical honesty

- Identity vs behaviour (section 7): about half of the composite's recent IC is reproduced by the ticker's own historical average of the score. That half is regime- and survivorship-exposed. The generalising half is led by momentum / RS leadership unusual for the name.
- No single factor passes a 5% false-discovery-rate test across the 86-factor zoo in either window. The recent window has roughly 24 independent 42-day periods; $|t|$ of 2-2.7 is the ceiling a true IC of 0.05-0.08 can reach there. The claims above rest on (a) coherent clusters pointing the same way, (b) survival after beta-neutralisation, (c) walk-forward reproduction, not on any one t-stat.
- Multiple-testing in the conditional tables: 860 bucket tests (expected max $|t|$ under the null about 3.2) and 946 per-sector tests. Cells near 3 are suggestive only.
- Survivorship: today's constituents. Ranks are robust to it; absolute forward-Sharpe levels (the deciles all sit near -1.1 in the recent window because SPY's own realised Sharpe was high) are not the point.
- Variant selection (5 ML configurations, 2 composite variants) is a mild in-sample choice and is disclosed; the picked composite is the beta-bucketed one.

4. How to use the ranking

- `final_score` is the within-beta-bucket composite percentile, so the top of the list mixes low-, mid- and high-beta leaders by design. Read it with `beta_bucket` : high-beta names are there for trend persistence (RS leading, 12-1 momentum, proximity to highs, recent 2x-off-low crossings); low-beta names are there for quiet volume-led accumulation.
- Expected magnitude: a top-decile vs bottom-decile difference of roughly 0.3 annualised Sharpe over the next 42 days, with the top decile beating the bottom in about 57% of windows. That is a real but modest edge; it is a screen that concentrates probability, not a signal that resolves individual names.
- Refit cadence: the factors turn over slowly (21d rank autocorrelation 0.7-0.9 for the ones that matter), so re-scoring weekly is sufficient; the walk-forward re-estimates weights annually and that was enough.
