

Vol Tape Regime v2

15 vol and rate indices and 38 ETFs, rank-based features, monotone trees refit yearly; every number on this page is out of sample. As of 2026-10-07. Feb to Jul 2020 excluded.

orange = risk-off side, blue = risk-on side

READING

IN

since 2026-07-14 · rule: OUT when the drawdown probability is above its trailing-756 95th percentile, back IN once below the 80th

90

stay-in dial = 100 minus the trailing percentile of the drawdown probability; the rule goes OUT at 5 or below and returns IN above 20

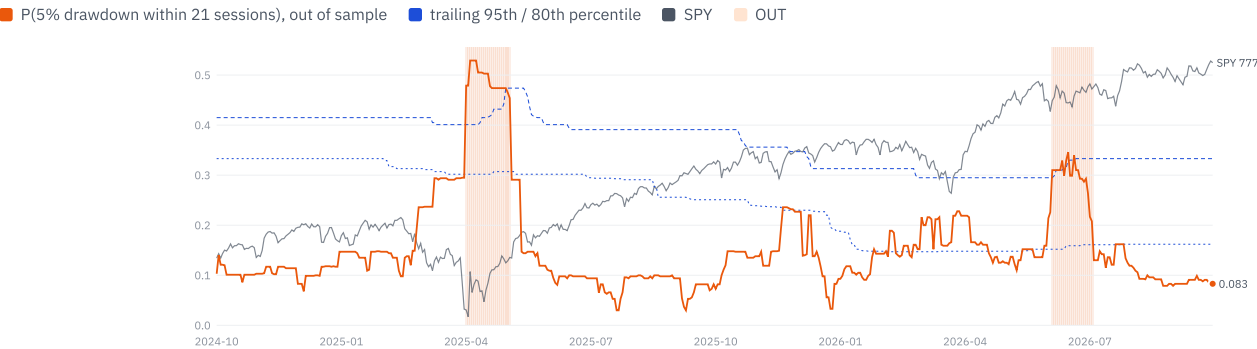

P(5% DRAWDOWN IN 21D)
0.083
trailing pct 10 · decile 4: historically 26% drew down 5%, mean next month -0.64%

P(5% RALLY IN 21D)
0.024
trailing pct 14 · decile 2: historically 2% rallied 5%, 10% drew down 5%

P(VOL EXPANDS 1.5X IN 21D)
0.041
trailing pct 42 · decile 4: historically 9% expanded, mean next month +0.61%

Not inside a vol episode. The drawdown probability sits at the 10th percentile of its own last three years; the rally probability at the 14th; the vol-expansion probability at the 42th. High readings of all three travel together (high vol is a two-tailed state), which is why the stay-in rule keys on the drawdown probability alone and re-enters quickly.

DRAWDOWN PROBABILITY, LAST TWO YEARS, WITH THE TRAILING THRESHOLDS THE RULE USES

WHY TODAY: THE FEATURES INSIDE EACH MODEL AND WHERE THEY SIT AGAINST THEIR OWN HISTORY

Each probability comes from 15 features chosen inside the last training window. Bars show each feature's trailing-rank distance from its median, signed by the direction the model is constrained to use: orange pushes the probability up, blue pushes it down.

Blue row: the reference rule shown above. Orange row: the rule that was pre-registered before the grid was run (vol expansion likely with no rebound setup) and failed, because an expected vol expansion is a low-drawdown state out of sample. The reference rule was chosen from the pre-specified grid after the grid was run, and its re-entry threshold was moved from the 60th to the 80th percentile after the slow version sat out 2009 and 2016; both versions are in the table. Drawdowns are in log units (-80 log = -55% price).

75% when IN, 100% on ADD: P_on >= q.80, held until < q.60	9.39	0.8	-21.7	0.7
75% when IN, 100% on ADD: P_on >= q.90, held until < q.60	9.03	0.79	-21.2	0.68
50% when IN, no ADD (the reserve never deployed)	5.6	0.82	-12.5	0.43
50% when IN, 100% on ADD: P_on >= q.80	7.02	0.76	-19.1	0.49
50% when IN, 100% on ADD: P_on >= q.90	6.44	0.76	-17.5	0.47
50% when IN, 100% on ADD: P_on >= q.80, held until < q.60	7.58	0.74	-21	0.53
50% when IN, 100% on ADD: P_on >= q.90, held until < q.60	6.85	0.71	-19.9	0.5

The rally condition as its own book. The sessions it selects (rally probability at or above its trailing 80th percentile, held until it falls below the 60th) earn 8.3 basis points a day against 5.1 for all IN sessions, on 22% of them. There is no free lunch without leverage: a book that holds 75% when IN and goes to 100% only on ADD makes 9.39% against 8.4% for the reserve never deployed and 11.21% for always full. It beats sitting on cash, not holding the position already held, so it is not on the instruction page: a note for deploying new money only.

The 2020 path. Every statistic on this page excludes Feb to Jul 2020 by design; here the frozen rules, fits and thresholds unchanged, are scored with the window included. Reference rule: max drawdown -25 log excluding the window and -25 log including it; it went OUT 2020-03-02 (SPY -8.6%), took 0.22 of the Feb 19 to Mar 23 decline, and came back IN 2020-06-02.

Every input is a rate of change of price (1 to 63 days, alone or against SPY), of volume, or of volatility (realized-vol rates of change, every implied-vol index and their ratios, the VIX premium's change); no levels. The target is what the user asked to detect: over the next 21 sessions SPY makes a lower high and a lower low than over the last 21. Out of sample it ranks that at about 0.79 (0.80 since 2023), partly because a month that has already turned down tends to keep the lower high; against a 5% drawdown it ranks only 0.57. Its last fit uses 5-, 10- and 21-day rates of change of SPY, QQQ, XLK, XLI, XLF and IWM. It replaces the levels-based drawdown leg, which protected 2008 and is kept in the record; the VIX-outrunning-VVIX leg starts in 2009, so a ROC-only system has no tested record in a 2008-type bear.

The signal: VIX's 21-day rate of change and the VIX/VVIX ratio's 21-day rate of change both in the top 10% of their trailing two years, live until VIX's 21-day rate of change falls back below its median. When VIX climbs and VVIX lags, the level of risk is being repriced; when VVIX keeps pace, it is a spike in tail insurance, and those mostly faded. It starts in 2009 because VVIX does. The split and the books are in-sample for the choice of this signal: it was found in this project's research and adopted after its record was seen, one of many cuts tried. August 2024 is a miss: VVIX kept pace and SPY still fell 6%. Since 2009 it has been live 42 times; 2020 is included in the books.

The fourteen rules that took the least of the eleven 15% declines (events: 2007-10-09 to 2008-03-10 -17.8%; 2008-05-19 to 2008-10-10 -37.5%; 2008-10-13 to 2008-10-27 -17.2%; 2008-11-04 to 2008-11-20 -24.9%; 2009-01-06 to 2009-03-09 -27.1%; 2010-04-23 to 2010-07-02 -15.7%; 2011-04-29 to 2011-10-03 -18.6%; 2018-09-20 to 2018-12-24 -19.3%; 2022-01-03 to 2022-06-16 -23.0%; 2022-08-16 to 2022-10-12 -16.7%; 2025-02-19 to 2025-04-08 -18.8%), plus the reference rule and buy-and-hold. "taken" 1.0 = took the whole decline, 0 = sidestepped it, above 1 = whipsawed into more than the decline. Totals are log-return points over 2006 to date. Every rule that sidesteps more of the declines gives up more outside them; none clears buy-and-hold by more than the reference rule does.

Onset rules: a vol-expansion alert (P_vol above its trailing 90th percentile at some point in the last 42 sessions) that becomes OUT only once SPY sits a given percent below its 63-session closing high, against the same price trigger with no vol filter. Re-entry on calmed probabilities, on a new 42-session closing high, or on either. "taken" is the mean share of the eleven 15% declines the book took; "false" counts OUT spells not followed by any 10% decline.

ROBUSTNESS: MODEL CAPACITY, RAW SINGLE FEATURES, YEAR-BLOCK BOOTSTRAP, AND A PERMUTATION TEST OF THE WHOLE PIPELINE

P_OFF PERMUTATION TEST

0.636 vs 0.497

real pooled AUC vs the mean of 20 null pipelines (sd 0.048, max 0.612) · z 2.9

P_VOL PERMUTATION TEST

0.748 vs 0.500

real pooled AUC vs the mean of 20 null pipelines (sd 0.025, max 0.533) · z 10.0

P_ON PERMUTATION TEST

0.789 vs 0.508

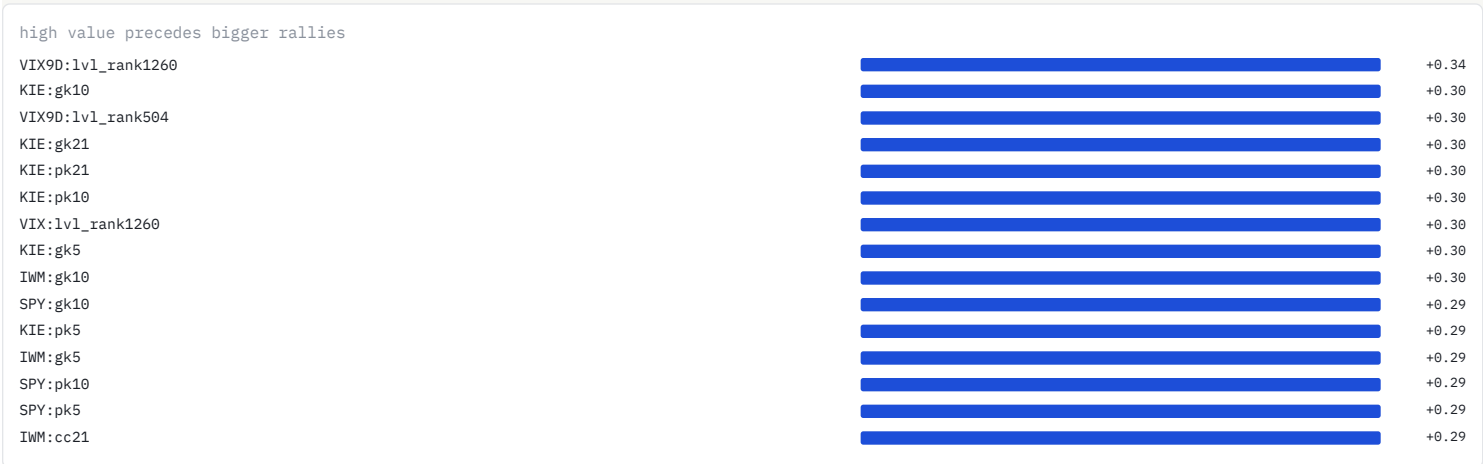

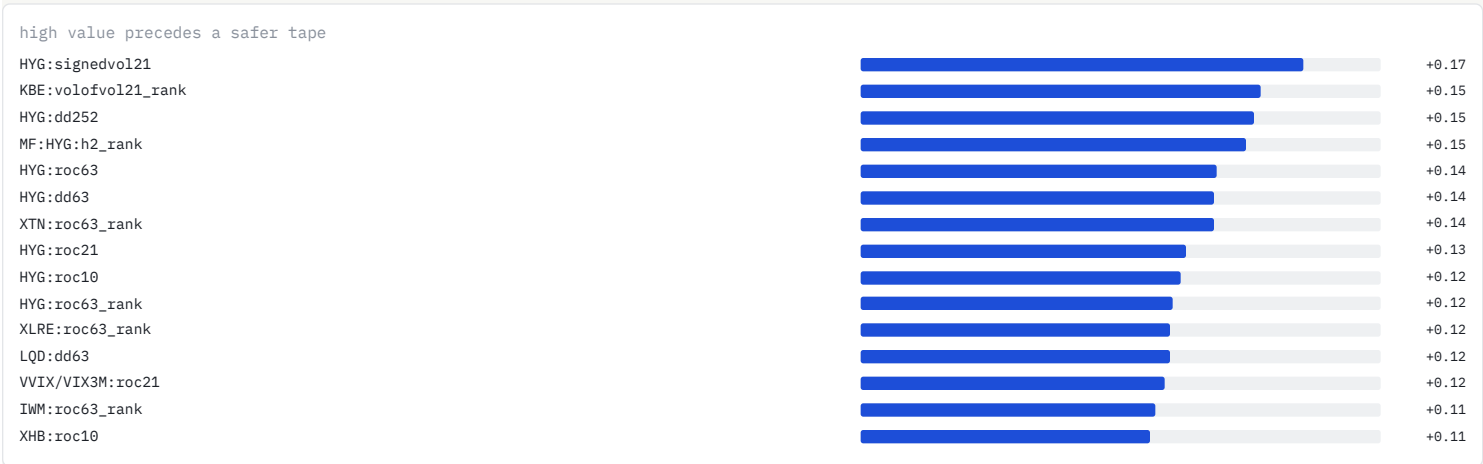

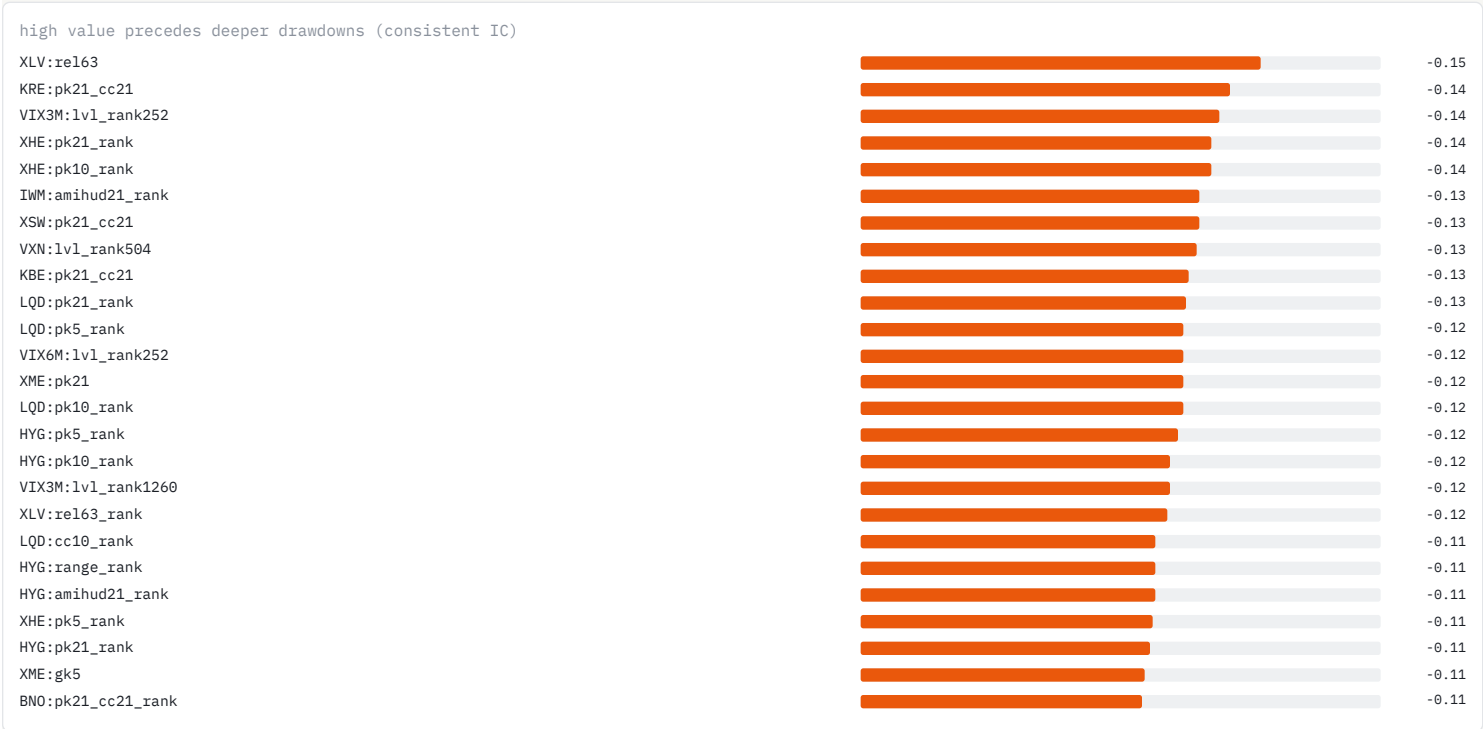

real pooled AUC vs the mean of 20 null pipelines (sd 0.056, max 0.622) · z 5.0

The permutation test shifts the label series by a random offset of at least a year and reruns the entire walk-forward pipeline, feature selection included; the resulting AUC is what selection and fitting produce from nothing.

Method: features are rates of change, ratios and trailing-504 percentile ranks built from daily OHLCV (close-to-close, Parkinson and Garman-Klass realized vol; volume and the volatility of volume; range compression; cross-sectional dispersion and correlation; implied over realized; equal-weight breadth; MF-DFA spectra). Models: 15 features chosen inside each training window by same-

signed rank correlation in both halves, depth-2 gradient-boosted trees constrained to be monotone in that sign, refit each January on data whose labels end before the test year. Thresholds are trailing quantiles of past out-of-sample values. KRE-based features are excluded from the candidate set by the user's direction. Nothing here assumes a distribution.
