

Generated from branch `claude/practical-hamilton-sspq2e` , file `pvv_score/results/REPORT.md` . Ranking as of the last completed session named in the tables.

PVV Score: price / volume / volatility selection for 21-63 day forward risk-adjusted returns

Universe: 503 Finviz S&P 500 constituents (file `data/universe_finviz.csv`), sector mapped to SPDR ETF.

Data: yfinance daily OHLCV, dividend/split adjusted, 2012-2026-10-05. Backtest window 2014-01-01 onward; the 2022-10 onward window ('recent') is the primary evidence per the mandate, the full window is the secondary check.

All statistics are out-of-sample where labelled OOS. Nothing here uses fundamentals, earnings or valuation.

1. Bottom line

- **The ranking is identity-neutral.** Every factor is expressed as the name's deviation from its own trailing 3-year norm (z), so a chronically strong, drawdown-free, high-Sharpe name (DELL, NVDA, LLY, PGR, BRK-B) scores near the middle unless its current price / volume / volatility behaviour is unusual for it. Weights are fitted walk-forward inside beta terciles. Every one of the 503 tickers has a score (section 6); names without 252 sessions of history are listed with the reason.
- **Out of sample (walk-forward 2017-2026), the state composite is the more robust of the two systems.** Recent window: 42d IC 0.039, 63d IC 0.056 (NW t 2.3); beta-neutral 63d IC 0.029 (t 2.4). Full window beta-neutral: 42d IC 0.017 (t 2.6), 63d 0.023 (t 2.9). The level-based composite had a slightly higher recent raw IC (0.047) but almost none of it survived beta-neutralisation (0.006) and half of it was ticker identity (section 7). Top-vs-bottom decile 42d Sharpe spread of the state composite: +0.22 annualised.
- **What precedes top-decile forward risk-adjusted windows, across all names (section 7b):** small but consistent pre-states. Pooled: 63d relative strength unusually WEAK for the name (bottom-quintile lift 1.08, top-quintile 0.85), dollar volume unusually low, no recent ignition day, downside-vol asymmetry unusually high, longer-than-usual time since the 21d high. That is a quiet, pulled-back, under-owned state, i.e. 1-3 month mean reversion, not breakout chasing. Mid-beta names add: 63d base unusually tight (lift 1.06 vs 0.84), downside vol unusually low, a recent ignition day. The identity layer (section 7) rewards persistent strength; the state layer rewards an unusual quiet pullback in a name. Both are real and they are different questions: which names, and when.
- The identity-heavy level composite and the LightGBM case-study model are kept in the files for comparison and are not used in the ranking.
- Compression / NR7 / Bollinger squeeze, ignition-day volume multiples, accumulation-day counts, gap behaviour, streaks and close-location factors showed no pooled 1-3 month signal as LEVELS. As STATES a few re-appear conditionally (tight base and ignition in mid beta); the rest stay flat.

2. Method

- **Targets.** For every (date, stock): realised Sharpe and Sortino of the stock over $t+1..t+h$ ($h = 21, 42, 63$) minus the same for SPY and for the stock's sector ETF (XLRE/XLC spliced to XLF/XLK before inception). Also the information-ratio form (Sharpe of stock-minus-SPY). The ML label is the per-date percentile of SPY-excess Sharpe averaged over the three horizons.
- **Eligibility (point-in-time).** Price $\geq \$5$, 63d median dollar volume $\geq \$10M$, ≥ 252 sessions of history. Survivorship caveat: the universe is today's constituents, so absolute levels are biased up; cross-sectional ranks are far less affected.
- **Factors.** 86 point-in-time factors in five families (price structure, volume, volatility, relative strength, run character) plus two user-described interaction setups. Each verified against hand calculations and a perturbation test for look-ahead (none).
- **Statistics.** Daily cross-sectional Spearman IC; Newey-West t-stats with lag = horizon because forward windows overlap; Benjamini-Hochberg across the 86-factor zoo; decile spreads in raw excess-Sharpe units; 21-day rank autocorrelation (turnover).
- **Conditioning.** Everything re-run inside trailing-beta terciles, 20d realised-vol terciles, sector groups (defensive / cyclical / growth), per sector, and with sector-neutral ranks.
- **Case-study model.** LightGBM trained walk-forward by calendar year (2017-2026), 63-day embargo, 2-year half-life time-decay weights, every 5th day sampled for training. Four pre-specified regularised variants were also run. Nearest-neighbour analogs (50 historical cases, max 3 per ticker) give each live name its realised-outcome evidence.
- **Composite.** Factor selection and weights re-estimated each year on training data only ($|\text{NW } t| \geq 1.5$ on the trailing 3y, sign agreement with full history, greedy de-duplication at $|\rho| > 0.7$, weights = recency-blended IC). Pooled and beta-bucketed variants.

3. Single-factor results (SPY-excess Sharpe, mean IC across 21/42/63d)

Power note: the recent window is $\sim 1,000$ sessions = roughly 24 independent 42-day windows, so $|t|$ around 2 is the attainable ceiling for a genuine IC of 0.05-0.07. **No factor survives Benjamini-Hochberg at 5% in either window.** The evidence is in coherent clusters, not individual rows.

d10_d1_spread_recent_42 is the annualised 42d Sharpe difference between the factor's top and bottom decile (recent window). autocorr_21 near 1 = slow factor; near 0 = daily-turnover factor.

Reading of the clusters

- **Trend-persistence / leadership cluster** (rs_lead_126 , mom_12_1 , dist_52w_low , up_capture_63 , days_since_2x_low negative, ceiling_2x_low positive): the only group with a consistent positive sign in the recent window and a positive sector-excess reading. Note ceiling_2x_low comes in with the OPPOSITE sign to the prior: names already 100% off their 52w low have continued to produce better forward Sharpe in 2022-2026. In the pooled sample the "ceiling" is not a ceiling.
- **Beta / correlation cluster** (beta_63 , beta_252 , corr_spy_63 , rv20 , dn_vol_63): positive in the recent window, flat over the full window, negative vs sector. This is the bull-regime beta bet, not stock selection. The composite and the model are therefore also evaluated beta-neutral (section 5).
- **Compression / dry-up setups** (range_comp_*, bbw_*, nr7_count_20 , vol_dry_*, dryup_x_tight): no pooled signal at these horizons. They show up only conditionally (section 4), in low-vol / defensive names.
- **Ignition / volume-burst factors** (ignition_mult_10 , vol_z_1 , big_vol_updays_net_21 , ignite_x_rs): no signal for 21-63d forward Sharpe in S&P 500 names. These are shorter-horizon or small-cap phenomena.
- **Short-term price factors** (ret_5 , clv_5 , streak_now , pos_in_20d_range): nothing. Daily-turnover factors with no 1-3 month payoff.

Multiple-testing note: 86 factors x 10 buckets = 860 tests; the expected maximum $|t|$ under the null is about 3.2, so single cells near 3 are not individually reliable. What is reliable is the pattern:

- **High beta / growth:** the trend-persistence cluster is strongest here (`mom_12_1` $t=3.6$ in the high-beta tercile, `days_since_52w_high` -2.5, `ceiling_2x_low` +2.7, `days_since_2x_low` -2.7). In high-beta names, buy strength, recent 2x-off-low crossings, and proximity to highs.
- **Low beta / low vol / defensive:** the sign of several price factors flips or dies, and volume-structure factors appear instead: `obv_price_div_63` +3.6 in defensives (volume leading price), `vol_dry_20_250` -2.1 in the low-vol tercile (dry-up works for utilities/staples-type names), `dvol_trend_21_126` -2.9 in low beta (quiet names outperform), `idio_vol_63` negative in low/mid beta. This is the DUK-vs-NVDA asymmetry the mandate anticipated, and it is why the composite is fitted per beta bucket.
- **Per sector** (`conditional_ic_42_per_sector.csv`): indicative only (18-80 names per date). Notable: Utilities `rs_lead_126` +3.1 and dry-up negative; Consumer Defensive `ceiling_2x_low` -3.2 (the ceiling DOES hold in staples) and compression factors positive; Financials show reversal (`ret_63` -2.3).

5. Out-of-sample predictive models (walk-forward 2017-2026)

Identity decomposition of the state composite (recent window, 42d): raw IC 0.039, persistent 0.027, deviation 0.039; correlation of today's rank with the name's own historical-average rank 0.42 (level composite: 0.58). The signal now sits in the deviation component.

6b. Final state-composite weights by beta bucket (z = deviation from the name's own 3y norm)

6c. All 503 tickers as of 2026-10-05

`state_score_pooled` = universe percentile of the state composite (the single sortable number).

`state_score` = percentile inside the name's beta bucket. `level_score` = the identity-heavy composite, for comparison. z columns are standard deviations vs the name's own history. `top_states` = the three readings contributing most to the score today. Sorted by `state_score_pooled`. The interactive version (filter, sort) is [universe_scores.html](#).

Rank correlation between level and state scores across the universe: 0.68.

7. Ticker identity vs. behaviour: how much of the signal generalises across tickers

Each reading is split, point-in-time, into **persistent** (the ticker's own expanding-window mean up to t-1: "this ticker is usually like this") and **deviation** (today's reading as a z-score against the ticker's own history: "this ticker is currently unusual"). IC of each component vs 42d SPY-excess Sharpe:

| factor | recent|raw | recent|persistent | recent|deviation | full|raw | full|persistent | full|deviation | |:-----
-----|-----:|-----:|-----:|-----:|-----:|-----:|-----:
-----:| | comp_bucketed | 0.047 | 0.053 | 0.035 | 0.015 | 0.017 | 0.016 | | | corr_spy_63 | 0.077 | 0.055 |

Pure ticker-identity predictors (long trailing Sharpe; the ticker's own trailing-year mean realised excess Sharpe):

predictor ic full ic recent t_nw full t_nw recent :----- -----: -----: -----
-----: past_xs_1y_mean 0.015 0.044 0.927 1.699 sharpe_252 0.013 0.042 0.758
1.615 sharpe_504 0.013 0.026 0.651 0.865 sharpe_756 0.024 0.034 1.266 1.303

Reading:

- The out-of-sample composite's recent IC (0.047) is matched by its persistent component alone (0.053); the deviation component carries 0.035. Today's composite rank correlates 0.580 with the ticker's own historical-average composite rank. **Roughly half to two thirds of what the ranking expresses is which tickers are chronically strong and stable, not a current state change.**
- A ticker's own trailing-year mean realised excess Sharpe predicts its next 42 days with IC 0.044 (t 1.7) in the recent window, about the same as the whole system. In 2022-10 to 2026 leadership persisted at the ticker level; much of the system's recent edge is that persistence.
- The persistent component is the part most exposed to survivorship bias (today's constituents are disproportionately the names that were chronically strong). Treat the identity half of the score as regime- and universe-dependent.
- The deviation component is the cleaner "behaviour predicts across tickers" evidence. It is weaker but real: 12-1 momentum unusually high for the name (IC 0.044, t 2.0, the only reading where the state component beats the identity component), RS-line leadership unusual for the name (0.031), correlation to SPY unusually high (0.058), idiosyncratic vol unusually low (-0.018). Proximity to 52w high, time since 20% drawdown and the dry-up interaction have no deviation signal pooled: they work only as identity, and only inside beta buckets.
- Volume factors: `obv_price_div_63` and `vol_dry_20_250` show up as identity, not state, pooled. The names that habitually have volume leading price, or habitually dry up, do better; a dry-up that is unusual for the name does not.

7b. Event study: the price / volume / volatility STATE that preceded top-decile forward windows

Episode = a (date, name) whose forward blended SPY-excess-Sharpe percentile was >= 0.90. Consecutive episode days of one name form a cluster (9,078 clusters since 2014, 2,828 since 2022-10). The state is measured **5 sessions before the cluster start**: the start day itself is selection-contaminated (by construction the day before was not a top-decile start, so the start is mechanically a local low; `z_ret_5` reads t = -59 at t-0 and ~0 at t-5, see `event_pre_episode_path_recent.csv`). Each state factor is ranked cross-sectionally per date; `mean_rank_excess` is the mean rank at t-5 minus 0.5 with a cluster-robust t; `lift_top_q` / `lift_bottom_q` = P(episode | factor in top / bottom quintile) / P(episode), over all days (no start selection).

Recent window, pooled (top 25 by |t|):

Reading:

- Effects are small ($|\text{rank excess}| \leq 0.02$ pooled, lifts 0.85-1.16) and statistically clear (2,800 independent clusters). There is no dramatic P/V/V signature 1-4 weeks before a top-decile 1-3 month window in S&P

500 names; there is a consistent tilt.

- The tilt is a **quiet pullback in the name**: 63d relative strength and 63d return unusually weak for the name (bottom-quintile lift 1.08-1.09), dollar volume unusually low (1.09), longer than usual since the 21d high (1.06), no recent ignition day (top-quintile lift of `days_since_ignition` 1.16), downside-vol asymmetry unusually high (1.07), beta and correlation to SPY unusually high. This is 1-3 month mean reversion with a capitulation flavour, and it is the opposite of what the level layer rewards.
- Mid beta adds structure that matches the mandate's hypotheses: 63d base unusually tight (bottom-quintile lift 1.06 vs top 0.84), downside vol unusually low (0.88 top), a recent ignition day (bottom-quintile 0.86), time since 2x-off-low crossing unusually long (1.31).
- Volume dry-up vs 250d, Bollinger / range compression, NR7 count, up/down volume ratio and OBV divergence as STATES: no pre-episode tilt pooled ($|t| < 1.5$). Accumulation-day count tilts slightly negative.
- These are the ingredients the state composite is allowed to pick from; what it actually selects each year is in `composite_state_weights_by_fold.csv`.

8. What to trust, what not to

Direct read of the evidence, in order of reliability.

1. What has out-of-sample support for 21-63d forward Sharpe in this universe

- Relative-strength leadership: `rs_lead_126` (RS line closer to its 6-month high than price is to its own). Walk-forward baseline, recent window: 42d IC 0.068 (NW t 2.4), 63d IC 0.082 (t 2.7); still 0.034-0.041 (t 2.1-2.2) after removing beta. The single most useful reading in the library.
- 12-1 momentum: recent beta-neutral 42d IC 0.048 (t 2.4), sector-excess IC 0.043 (t 2.1). Dead over 2014-2021 (full-window IC 0.005), alive since 2022-10. Consistent with the regime shift the mandate describes.
- Beta-bucketed walk-forward composite: recent 42d IC 0.047 (t 1.5), 63d 0.065 (t 1.9), top-minus-bottom decile 42d Sharpe spread +0.29 annualised with near-monotone deciles. The pooled composite has nothing (recent IC negative). Conditioning on beta is what makes the composite work. Its beta-neutral IC is small (0.006-0.015): inside each bucket it still leans on correlation / up-capture type factors, so part of its recent edge is bull-regime beta.
- Low-beta / defensive names respond to volume structure, not price structure: OBV leading price (`obv_price_div_63`, t 3.6 in defensives), volume dry-up vs 250d (`vol_dry_20_250`, t -2.1 in the low-vol tercile), falling dollar volume (`dvol_trend_21_126`, t -2.9 in low beta). Treat as a cluster, not three independent facts.

2. What did not show signal at this horizon in S&P 500 names (tested, not assumed)

- Compression setups (daily-range percentile, Bollinger width, NR7 clusters, base tightness), pooled: IC within +/-0.015 in every window and horizon. They only appear inside the low-vol / defensive bucket. The "compression then expansion" sequence factor is flat everywhere.
- Ignition-day volume multiple, volume z-score, big-volume up-day counts, the ignition x RS interaction: flat. Nothing in a 1-10 day volume burst predicts the next 1-3 months of risk-adjusted return here.

- Accumulation/distribution day counts, up/down volume ratio: flat pooled, mildly negative in places.
- Higher-low cadence, close location value, gap frequency, streaks, 20d range position: flat.
- The 100%-off-low "ceiling": wrong sign pooled and in high beta (names already 2x off the low kept producing better Sharpe, t +2.3 to +2.7); right sign only in Consumer Defensive (t -3.2). Do not use it as a universal exclusion.
- The LightGBM case-study model, in all five configurations: recent-window 42d IC between -0.001 and +0.023, none significant, every variant below the two single-factor baselines. A great 2019 (IC 0.11-0.14) and nothing stable since. Non-linear interaction mining over 86 factors does not beat two robust factors at this horizon with ~10 years of 500-name data. The analog columns in the ranking are therefore descriptive evidence per name, not a forecast.

3. Statistical honesty

- Identity vs behaviour (section 7): about half of the composite's recent IC is reproduced by the ticker's own historical average of the score. That half is regime- and survivorship-exposed. The generalising half is led by momentum / RS leadership unusual for the name.
- No single factor passes a 5% false-discovery-rate test across the 86-factor zoo in either window. The recent window has roughly 24 independent 42-day periods; $|t|$ of 2-2.7 is the ceiling a true IC of 0.05-0.08 can reach there. The claims above rest on (a) coherent clusters pointing the same way, (b) survival after beta-neutralisation, (c) walk-forward reproduction, not on any one t -stat.
- Multiple-testing in the conditional tables: 860 bucket tests (expected max $|t|$ under the null about 3.2) and 946 per-sector tests. Cells near 3 are suggestive only.
- Survivorship: today's constituents. Ranks are robust to it; absolute forward-Sharpe levels (the deciles all sit near -1.1 in the recent window because SPY's own realised Sharpe was high) are not the point.
- Variant selection (5 ML configurations, 2 composite variants) is a mild in-sample choice and is disclosed; the picked composite is the beta-bucketed one.

4. How to use the ranking

- `final_score` is the within-beta-bucket composite percentile, so the top of the list mixes low-, mid- and high-beta leaders by design. Read it with `beta_bucket` : high-beta names are there for trend persistence (RS leading, 12-1 momentum, proximity to highs, recent 2x-off-low crossings); low-beta names are there for quiet volume-led accumulation.
- Expected magnitude: a top-decile vs bottom-decile difference of roughly 0.3 annualised Sharpe over the next 42 days, with the top decile beating the bottom in about 57% of windows. That is a real but modest edge; it is a screen that concentrates probability, not a signal that resolves individual names.
- Refit cadence: the factors turn over slowly (21d rank autocorrelation 0.7-0.9 for the ones that matter), so re-scoring weekly is sufficient; the walk-forward re-estimates weights annually and that was enough.
